

Memory card: what is stored, when it is read, and what it costs

External memory is inspectable. It helps rerank candidates without changing the frozen model.

Memory type

External road-sign / object-patch memory

Write

After the first-visit episode, before reranking

Use

Select the memory-consistent continuation

Code locations

scripts/.../object_patch_memory_reranker.py
results/final/object_patch_rerank_seed1_8.csv

Limitation

External reranking only; no internal conditioning

Memory unit

One crop, one frame cue, or one patch bundle

Read

During candidate comparison and selection

Stored fields

crop image, seed id, frame id, scene tag, score, source path

Cost

Small JSONL / image storage, light rerank runtime,
no extra base-model GPU memory

Future upgrade

Dynamic memory and internal conditioning

Storage

Write only compact evidence: crop images, scores, and metadata.
The memory bank remains easy to inspect.

Runtime / GPU

Reranking runs outside the frozen world model.
The model attention and weights do not change.

Upgrade path

If this were extended later, the next step would be learned dynamic memory plus internal conditioning.

This memory is case-study evidence: useful for selection, but not a claim of a changed internal world model.
